1 Introduction

1.1. Scope of the Document

This document presents the AT Commands Set for Quectel cellular engine MC20.

1.2. AT Command Syntax

The “AT” or “at” prefix must be set at the beginning of each command line. To terminate a command line enter **<CR>**. Commands are usually followed by a response that includes **<CR><LF><response><CR><LF>**. Throughout this document, only the responses are presented, **<CR><LF>** are omitted intentionally.

The AT Commands Set implemented by MC20 is a combination of GSM07.05, GSM07.07 and ITU-T recommendation V.25ter as well as the AT commands developed by Quectel.

All these AT commands can be split into three categories syntactically: “**basic**”, “**S parameter**”, and “**extended**”. They are listed as follows:

- **Basic syntax**

These AT commands have the format of “**AT<x><n>**”, or “**AT&<x><n>**”, where “**<x>**” is the command, and “**<n>**” is/are the argument(s) for that command. An example of this is “**ATE<n>**”, which tells the DCE whether received characters should be echoed back to the DTE according to the value of “**<n>**”. “**<n>**” is optional and a default will be used if it is missing.

- **S parameter syntax**

These AT commands have the format of “**ATS<n>=<m>**”, where “**<n>**” is the index of the **S** register to set, and “**<m>**” is the value to assign to it. “**<m>**” is optional; if it is missing, then a default value is assigned.

- **Extended syntax**

These commands can be operated in several modes, as following table:

Table 1: Types of AT Commands and Responses

Test Command	AT+<x>=?	This command returns the list of parameters and value ranges set by the corresponding Write Command or internal processes.
Read Command	AT+<x>?	This command returns the currently set value of the parameter or parameters.
Write Command	AT+<x>=<...>	This command sets the user-definable parameter values.
Execution Command	AT+<x>	This command reads non-variable parameters affected by internal processes in the GSM engine.

1.2.1. Combining AT Commands on the Same Command Line

You can enter several AT commands on the same line. In this case, you do not need to type the “AT” or “at” prefix before every command. Instead, you only need to type “AT” or “at” at the beginning of the command line. Please note that use a semicolon as command delimiter.

The command line buffer can accept a maximum of 256 characters. If the input characters exceeded the maximum then no command will be executed and TA will return “ERROR”.

1.2.2. Entering Successive AT Commands on Separate Lines

When you need to enter a series of AT commands on separate lines, please note that you need to wait the final response (for example OK, CME error, CMS error) of the last AT command you entered before you enter the next AT command.

1.3. Supported Character Sets

The MC20 AT command interface defaults to the GSM character set. The MC20 supports the following character sets:

- GSM
- UCS2
- HEX
- IRA
- PCCP437
- 8859-1

The character set can be configured and interrogated using the “AT+CSCS” command (GSM 07.07). The character set is defined in GSM specification 07.05. The character set affects transmission and reception

of SMS and SMS Cell Broadcast Messages, as well as the entry and display of phone book entries text field and SIM Application Toolkit alpha strings.

1.4. Flow Control

Flow control is very important for correct communication between the GSM engine and the DTE. In cases such as a data or fax call, the sending device is transferring data faster than the receiving side ready to accept. When the receiving buffer reaches its capacity, the receiving device should be able to cause the sending device to pause until it catches up.

There are basically two approaches to achieve data flow control: software flow control and hardware flow control. MC20 supports both two kinds of flow control.

In multiplex mode, it is recommended to use the hardware flow control.

The default flow control approach of MC20 is disabled.

1.4.1. Software Flow Control (XON/XOFF Flow Control)

Software flow control sends different characters to stop (XOFF, decimal 19) and resume (XON, decimal 17) data flow. It is quite useful in some applications that only use three wires on the serial interface.

The default flow control approach of MC20 is disabled. To enable software flow control in the DTE interface and within GSM engine, type the following AT command:

AT+IFC=1, 1<CR>

This setting is stored in volatile memory, for use after restart. **AT+IFC=1, 1<CR>** should be stored to the user profile with **AT&W<CR>**.

Ensure that all communication software packages (e.g. ProComm Plus, Hyper Terminal or WinFax Pro) use software flow control.

NOTE

Software Flow Control should not be used for data calls where binary data will be transmitted or received (e.g. TCP/IP), because the DTE interface may interpret binary data as flow control characters.

1.4.2. Hardware Flow Control (RTS/CTS Flow Control)

The default flow control approach of MC20 is disabled. To enable hardware flow control (RTS/CTS flow control) in the DTE interface and within GSM engine, type the following AT command:

AT+IFC=2, 2<CR>

This setting is stored volatile, for use after restart. **AT+IFC=2, 2<CR>** should be stored to the user profile with **AT&W<CR>**.

Hardware flow control achieves the data flow control by controlling the RTS/CTS line. When the data transfer is suspended, the CTS line is set inactive until the transfer from the receiving buffer has been completed. When the receiving buffer is ready to receive more data, CTS goes active once again.

To achieve hardware flow control, ensure that the RTS/CTS lines are available on your application platform.

1.5. Unsolicited Result Codes

A URC is a report message sent from the ME to the TE. An unsolicited result code can be delivered automatically when an event occurs, reflect changes in system state, or act as the result of a query the ME received before. It is often delivered due to occurrences of errors in executing the queries. However, a URC is not issued as a direct response to an executed AT command. AT commands have their own implementations to validate inputs such as “OK” or “ERROR”.

Typical URCs may be information about incoming calls, received SMS, changing temperature, status of the battery, etc. A summary of URCs is listed in **Chapter 16.6**.

When sending a URC, the ME activates its Ring Interrupt (Logic “l”), i.e. the line goes active low for a few milliseconds. If an event which delivers a URC coincides with the execution of an AT command, the URC will be output after command execution has been completed.

19200
28800
38400
57600
115200

NOTES

1. The default configuration of **AT+IPR** is adaptive baud rate enabled (**AT+IPR=0**).
2. If a fixed baud rate is set, make sure that both TE (DTE, usually external processor) and TA (DCE, Quectel GSM module) are configured to the same rate. If adaptive baud rate is enabled, the TA could automatically recognize the baud rate currently used by the TE after receiving “**AT**” or “**at**” string.
3. The value of **AT+IPR** cannot be restored with **AT&F** and **ATZ**, but it is still storable with **AT&W** and visible in **AT&V**.
4. In multiplex mode, the baud rate cannot be changed by the write command **AT+IPR=<rate>**, and the setting is invalid and not stored even if **AT&W** is executed after the write command.
5. A selected baud rate takes effect after the write commands are executed and acknowledged by “OK”.

Example

```

AT+IPR=115200 //Set fixed baud rate to 115200bps
OK
AT&W //Store current setting, that is, the serial
//communication speed is 115200bps after restart
//module

OK
AT+IPR?
+IPR: 115200

OK

```

3.6.1. Adaptive Baud Rate

To take advantage of adaptive baud rate mode, specific attention must be paid to the following requirements:

1. Adaptive baud rate synchronization between TE and TA.
 - Ensure that TE and TA are correctly synchronized and the baud rate used by the TE is detected by the TA. The baud rate can be synchronized simply by use an “**AT**” or “**at**” string. This is

necessary after customer activates adaptive baud rate or when customer starts up the module with adaptive baud rate enabled.

- It is recommended to wait for 2 to 3 seconds before sending the first “AT” or “at” string after the module is started up with adaptive baud rate enabled. Otherwise undefined characters might be returned.
2. Restriction on adaptive baud rate operation.
- The serial interface shall be used with 8 data bits, no parity and 1 stop bit (factory setting).
 - The command “A” can’t be used.
 - Only the string “AT” or “at” can be detected (either “AT” or “at”).
 - URCs that may be issued before the TA detect a new baud rate by receiving the first AT character, and they will be sent at the previously detected baud rate.
 - If TE’s baud rate is changed after TA has recognized the earlier baud rate, loss of synchronization between TE and TA would be encountered and an “AT” or “at” string must be re-sent by TE to regain synchronization on baud rate. To avoid undefined characters during baud rate resynchronization and the possible malfunction of resynchronization, it is not recommended to switch TE’s baud rate when adaptive baud rate is enabled. Especially, this operation is forbidden in data mode.
3. Adaptive baud rate and baud rate after restarting.
- In the adaptive baud rate mode, the detected baud rate is not saved. Therefore, resynchronization is required after restarting the module.
 - Unless the baud rate is determined, an incoming CSD call can’t be accepted. This must be taken into account when adaptive baud rate and auto-answer mode (**AT\$0#0**) are enabled at the same time, especially if SIM PIN 1 authentication is done automatically and the setting **AT\$0#0** is stored to the user profile with **AT&W**.
 - Until the baud rate is synchronized, URCs after restarting will not be output when adaptive baud rate is enabled.
4. Adaptive baud rate and multiplex mode.
- If adaptive baud rate is active, it is not recommended to switch to multiplex mode.
5. Adaptive baud rate and Windows modem.
- The baud rate used by Windows modem can be detected while setting up a dial-up GPRS/CSD connection. However, some Windows modem drivers switch TE’s baud rate to default value automatically after the GPRS call is terminated. In order to prevent no response to the Windows modem when it happens, it is not recommended to establish the dial-up GPRS/CSD connection in adaptive baud rate mode.
 - Based on the same considerations, it is also not recommended to establish the FAX connection in adaptive baud rate mode for PC FAX application, such as WinFax.

NOTE

To assure reliable communication and avoid any problem caused by undetermined baud rate between DCE and DTE, it is strongly recommended to configure a fixed baud rate and save it instead of using adaptive baud rate after start-up.

6 Network Service Commands

6.1. AT+COPS Operator Selection

AT+COPS Operator Selection

Test Command

AT+COPS=?

Response

TA returns a list of quadruplets, each representing an operator present in the network. Any of the formats may be unavailable and should then be an empty field. The list of operators shall be in the order of: home network, networks referenced in SIM, and other networks.

+COPS: (list of supported <stat>, long alphanumeric <oper>, short alphanumeric <oper>, numeric <oper>s)[,(list of supported <mode>s),(list of supported <format>s)]

OK

If error is related to ME functionality:

+CME ERROR: <err>

Read Command

AT+COPS?

Response

TA returns the current mode and the currently selected operator. If no operator is selected, <format> and <oper> are omitted.

+COPS: <mode>[,<format>[,<oper>]]

OK

If error is related to ME functionality:

+CME ERROR: <err>

Write Command

AT+COPS=<mode>[,<format>[,<oper>]]

Response

TA forces an attempt to select and register on the GSM network operator. If the selected operator is not available, no other operator shall be selected (except <mode>=4). The format of selected operator name shall apply to further read commands (**+COPS?**).

	OK
	If error is related to ME functionality: +CME ERROR: <err>
Maximum Response Time Reference GSM 07.07	75s, determined by network.

Parameter

<stat>	0 Unknown 1 Operator available 2 Operator current 3 Operator forbidden
<oper>	Operator in format as per <mode>
<mode>	0 Automatic mode; <oper> field is ignored 1 Manual operator selection; <oper> field shall be present 2 Manual deregister from network 3 Set only <format> (for read command +COPS?) – not shown in read command response 4 Manual/automatic selected; if manual selection fails, automatic mode (<mode>=0) is entered
<format>	0 Long format alphanumeric <oper> ; can be up to 16 characters long 1 Short format alphanumeric <oper> 2 Numeric <oper> ; GSM Location Area Identification number

NOTES

- This write command is used to choose and register the GSM network operator. The setting of **<mode>** allows ME to determine whether automatic or manual network selection shall be used.
 - When **<mode>=0**, the ME searches for the operator which shall be used automatically.
 - When **<mode>=1**, the ME forces to register the selected **<oper>**. If the **<oper>** is invalid, the ME remains unregistered; until **<mode>=0**, the ME can register again. If restart module, the ME is still under **<mode>=1** and there is no RPLMN. The ME will also be Not Registered on Network condition, until the mode is changed via the command to automatic registration mode.
 - When **<mode>=4**, if the ME fails to register to this operator, then it starts to select another operator automatically.
- This command setting is saved to NVRAM automatically.

Example

AT+COPS=?	//List all current network operators
+COPS: (2,"CHINA MOBILE","CMCC","46000"),(3,"CHINA UNICOM GSM","UNICOM","46001")

<lac>		Location area code in hex format
<cellid>		Cell ID in hex format
<bcch>		Absolute Radio Frequency Channel Number of Broadcast Control Channel (BCCH)
<bsic>		Base station identity code
<dbm>		Receive signal level in dBm unit
<c1>		C1 value
<c2>		C2 value
<txp>		Maximum TX power level when accessing on a CCH
<rla>		Minimum receiving level permitted to access the system
<ts>		TimeSlots
<maio>		MAIO value
<hsn>		HSN value
<tch>		ARFCN of TCH, 'h' figure hopping
<ta>		Timing Advance, range 0~63
<rxq_sub>		RX quality(sub), range 0~7
<rxq_full>		RX quality(full), range 0~7
<nccell>		Number of neighboring six cell ID 1~6
<arfcn>		Absolute radio frequency channel number

NOTES

The following radio settings to be updated are stored in non-volatile memory.

1. When mode is 2, auto URCs are reported per 5 seconds.
2. The **<lac>** and **<cellid>** parameters are available in hex format, and these parameters are in decimal.
3. If the cell information is not detected, the parameter is replaced by 'x' char.

4. If the detecting is not expert mode, parameters <tch>, <ts>, <maio>, <hsn>, <ta>, <rxq_sub> and <rxq_full> will not display the parameter value while are replaced by 'x' char.
5. During the network connecting, if the hopping frequency is supported by the network, the channel of TCH is instable. Using the 'h' figure <tch> under this mode.
6. Under expert mode, when the <c1> and <c2> of the serving cell cannot be updated, using the '-1' figure to display the illegal value. At the same time, <txp> and <rla> parameters cannot be updated in a certain condition, all the same holding the value of idle mode. This is because ME cannot be updated in this mode. ME cannot update the selection of cell and reselection of the parameter. When the connecting is over, mobile device will go back to idle mode and offer the correct value.
7. If TA can report the information of the neighboring cell, the URCs of six neighboring cell should be reported. If some cells cannot be measured, the 'x' char will be filled in the parameter of these cells.
8. Under the special mode, <c1> and <c2> parameters of the neighboring cell may be measured, and then an unmeaning value will be reported. When <mcc>, <mnc>, <lac> and <cellid> parameters of the neighboring cell cannot be measured, the 'x' char will be filled in these parameters of all the six cells.
9. The command does not report the RX level and the RX quality. The "AT+CSQ" command can be used to query the values of RX level and RX quality.
10. The "AT+QSPCH" command can be used to re-query the type of the voice channel during calling (FR, HR, EFR, AMR_FR, AMR_HR).
11. The maximum record number of BA measured result list is 32. If any of the BCCH cannot get the BSIC value, the BSIC will show 'x' instead. The measured list only includes the measured BCCH in the BA list, not the whole BA list.

2. Parameter "l" and "i" are applicable for cases where there are no *# codes within the dial string.
3. <n> is the default value for last number that can be dialed by **ATDL**.
4. *# codes sent with **ATD** are treated as voice calls. Therefore, the command must be terminated with a semicolon ";".
5. See **ATX** command for setting result code and call monitoring parameters.
6. Responses returned after dialing with **ATD**
 - For voice call, two different responses modes can be determined. TA returns "OK" immediately either after dialing was completed or after the call was established. The setting is controlled by **AT+COLP**. Factory default is **AT+COLP=0**, which causes the TA returns "OK" immediately after dialing was completed; otherwise TA will returns "OK", "BUSY", "NO DIAL TONE", "NO CARRIER".
7. Using **ATD** during an active voice call:
 - When a user originates a second voice call while there is already an active voice call, the first call will be automatically put on hold.
 - The current states of all calls can be easily checked at any time by using the **AT+CLCC** command.

Example

ATD10086;	//Dialing out the called party's number
OK

ATH[n]	Disconnect existing call by local TE from command line and terminate call. OK
Maximum Response Time	90s, determined by network.

NOTE

OK is issued after circuit 109 (DCD) is turned off, if it was previously on.

7.4. +++ Switch from Data Mode to Command Mode

+++ Switch from Data Mode to Command Mode

Execution Command

+++

Response

This command is only available during TA is in data mode, such as, a GPRS connection and a transparent TCPIP connection. The “+++” character sequence causes the TA to cancel the data flow over the AT interface and switch to command mode. This allows you to enter AT command while maintaining the data connection with the remote server or, accordingly, the GPRS connection.

OK

Maximum Response Time

300ms

Reference

V.25ter

NOTES

1. To prevent the “+++” escape sequence from being misinterpreted as data, it should comply to following sequence:
 - No characters entered for T1 time (0.5 seconds).
 - “+++” characters entered with no characters in between. For PPP online mode, the interval between two “+” MUST be less than 1 second and for a transparent TCPIP connection, the interval MUST be less than 20ms.
 - No characters entered for T1 time (0.5 seconds).
 - Switch to command mode, otherwise go to step 1.
2. To return from command mode back to data or PPP online mode: Enter **ATO**
 - Another way to change to command mode is through DTR, see **AT&D** command for the details.

<mode>	A string parameter which indicates the connection type "TCP" Establish a TCP connection "UDP" Establish a UDP connection
<IP address>	A string parameter that gives the address of the remote server in dotted decimal style.
<port>	The port of the remote server 0-65535

<domain name> A string parameter which represents the domain name address of the remote server

NOTES

1. This command is allowed to establish a TCP/UDP connection only when the state is IP INITIAL, IP STATUS or IP CLOSE. So it is necessary to process "AT+QIDEACT" or "AT+QICLOSE" before establishing a TCP/UDP connection with this command when the state is not IP INITIAL, IP STATUS or IP CLOSE.
2. If **AT+QIMUX** was set as 0 and the current state is CONNECT OK, which means the connection channel is used, it will reply "ALREADY CONNECT" after issuing the Write Command.

Write Command 1) When AT+QIMUX=0 AT+QISEND=<length> 2) When AT+QIMUX=1 AT+QISEND=<index>[,<length>]	Response This command is used to send fixed-length data or send data on the given socket (defined by <index>). If connection is not established or disconnected: ERROR If sending succeeds: SEND OK If sending fails: SEND FAIL

Maximum Response Time	300ms
Reference Quectel	

Parameter

- <index>** The index of the socket for sending data. This parameter is necessary only if **AT+QIMUX** was set as 1 (refer to **AT+QIMUX**). When **AT+QIMUX** was set as 0, the parameter must be omitted
- <length>** A numeric parameter which indicates the length of data to be sent, it must be less than 1460

NOTES

1. This command is used to send data on the TCP or UDP connection that has been established already. ‘Ctrl+Z’ is used as a termination symbol. ESC is used to cancel sending data.
2. The maximum length of the data to input at a time is 1460.
3. There are at most 1460 bytes that can be sent each time.
4. Only send data at the status of connection, otherwise respond with **ERROR**.
5. **SEND OK** means the data have been put into the send window to send rather than it has received the ACK message for the data from the remote node. To check whether the data has been sent to the remote node, it is necessary to execute the command **AT+QISACK** to query it.

Parameter

<index> The index of the socket for sending data. This parameter is necessary only if **AT+QIMUX** was set as 1 (refer to **AT+QIMUX**). When **AT+QIMUX** was set as 0, the parameter MUST be omitted

NOTES

1. Execution Command **AT+QICLOSE**:

- If **QISRVC** is 1 (please refer to **AT+QISRVC**) and **QIMUX** is 0 (please refer to **AT+QIMUX**), this command will close the connection in which the module is used as a client.
- If **QISRVC** is 1 and **QIMUX** is 1, it will return ERROR.
- If **QISRVC** is 2, **QIMUX** equals 0, the module is used as a server and some clients have been connected to it, this command will close the connection between the module and the remote client.
- If **QISRVC** is 2, **QIMUX** is 0 and the module is in listening state without any client, this command will cause the module to quit the listening state.
- If **QISRVC** is 2, **QIMUX** is 1 and the module is used as a server, this command will close all the income connection and cause the module to quit the listening state.

2. Write Command **AT+QICLOSE=<index>**:

- This command is valid only if **QIMUX** is 1.
- If **QISRVC** is 1 and **QIMUX** is 1, this command will close the corresponding connection according to **<index>** and the module is used as a client in the connection.
- If **QISRVC** is 2 and **QIMUX** is 1, this command will close the incoming connection according to **<index>**.

3. If **QISRVC** is 1 and **QIMUX** is 0, **AT+QICLOSE** only closes the connection when the status is CONNECTING or CONNECT OK, otherwise respond with ERROR. After closing the connection, the status is IP CLOSE.

- <esc> Whether to turn on the escape sequence or not; default is TRUE

NOTES

1. <WaitTm> and <SendSz> are two conditions to send data packet.
2. Firstly, if the length of the input data from UART is greater than or equal to <SendSz>, the TCPIP stack will send the data by length <SendSz> to the remote.
3. Secondly, if the length of the input data from UART is less than <SendSz>, and the idle time keeps beyond the time defined by <WaitTm>, the TCPIP stack will send all the data in the buffer to the remote.
